5.PROJECT DEVELOPMENT PHASE:

The Project Development Phase is the stage where the planned design and requirements are implemented in the ServiceNow platform. In this phase, the system is developed by performing the necessary configurations and steps to automate the employee data import process and improve incident management.

The development of this project involves creating employee records, importing the data into ServiceNow, mapping the fields correctly, displaying related information in incident forms, and customizing the priority value.

Step 1: Creating Employee Data

The first step in the development process is to create employee data in a spreadsheet.

Open Google Sheets or Microsoft Excel

Create columns for the required employee fields

The fields include:

- Name
- Email
- Department
- Manager
- Manager Email

Enter sample employee records

Save the file and download it in CSV or Excel format

This file will be used to import employee data into the ServiceNow system.

Step 2: Importing Data into ServiceNow

In this step, the employee data file is uploaded into the ServiceNow platform using the Import Sets feature.

- Open ServiceNow
- Go to All → System Import Sets → Load Data
- Create a new Import Table
- Upload the employee data file
- The system stores the uploaded records in the import table

This table acts as a temporary storage area for the imported data.

Step 3: Creating Transform Map

After importing the data, a Transform Map is created to move the data from the import table to the target table.

- Navigate to System Import Sets → Transform Maps
- Create a new Transform Map

- Select the Source Table (Import Employee Data)
- Select the Target Table (User – sys_user)
- Use Auto Match Fields to automatically map fields
- Use Mapping Assist to map additional fields such as manager

This step ensures that the employee data is correctly transferred to the target table.

Step 4: Transforming the Data

Once the fields are mapped, the transform process is executed.

- Click on Transform
- The system moves the data from the import table to the User table
- New employee records are created automatically in the system
- Verify that the data has been inserted successfully

Step 5: Configuring Incident Form using Dot Walking

In this step, the incident form is modified to display employee information automatically.

- Open the Incident Form
- Go to Configure → Form Layout
- Add fields such as:
- Assigned To.Department
- Assigned To.Email
- Assigned To.Manager
- Save the form layout
- Using Dot Walking, the system retrieves related employee details when a user is assigned to an incident.

Step 6: Customizing Priority using Dictionary Override

The final development step is customizing the priority field in the incident table.

- Navigate to the Dictionary Override option
- Select the Incident Table
- Choose the Priority Field
- Enable Override Default Value
- Set the default priority value to 3 – Moderate
- Save the changes

This ensures that incidents have a different default priority compared to the parent task table.

Development Outcome

After completing these development steps:

- Employee data is automatically imported into ServiceNow
- Employee details appear automatically in the incident form
- The incident priority value is customized according to the project requirement

This development process improves efficiency, reduces manual work, and enhances the overall incident management workflow.
