3.PROJECT DESIGN PHASE:

The Project Design Phase focuses on designing the structure and workflow of the system. In this phase, the components of the system and the way they interact with each other are defined. The design helps in understanding how the data flows through the system and how different features of ServiceNow are used to complete the project.

The design of this project mainly involves importing employee data, mapping the fields correctly, retrieving related information in incident forms, and customizing the priority field for incidents.

System Components:

The following components are used in the design of the system:

- Import Sets
- Import Sets are used to bring external data into the ServiceNow platform.
- It allows data to be uploaded from files such as Excel or CSV
- The imported data is first stored in a temporary import table
- This table acts as a staging area before the data is moved to the final table

Transform Map:

Transform Map is used to transfer data from the import table to the target table. It defines the mapping between source fields and target fields

It ensures that the correct data is inserted into the correct columns

It uses Auto Match Fields and Mapping Assist for easier field mapping

Dot Walking:

Dot Walking is a feature used to retrieve related information from referenced tables. It allows access to fields in related records

It helps display employee details such as:

- Department
- Manager
- Email

This information appears automatically in the Incident Form.

Dictionary Override:

Dictionary Override is used to change the properties of fields in extended tables. It allows modification of field attributes

In this project, it is used to change the default value of the priority field

The priority value is changed to 3 – Moderate in the incident table

Data Flow of the System:

The system follows a simple data flow process:

- Employee data is created in Excel or Google Sheets
- The data file is uploaded into ServiceNow Import Sets
- The data is stored in the Import Table
- The Transform Map transfers the data to the User table
- When an incident is created, Dot Walking retrieves employee details
- Dictionary Override modifies the default priority value for incidents

System Architecture Overview:

The system design follows a simple architecture:

- External Data Source – Employee data file (Excel/CSV)
- ServiceNow Import Set Table – Temporary storage of imported data
- Transform Map – Field mapping between tables
- User Table (sys_user) – Final storage of employee records
- Incident Module – Displays employee information and manages incidents

This design ensures smooth data import, accurate field mapping, and efficient incident management in automatic employee data.
